18-3-2024 until 22-3-2024

Lecture M7 – Attosecond molecular physics

Max-Born-Institut

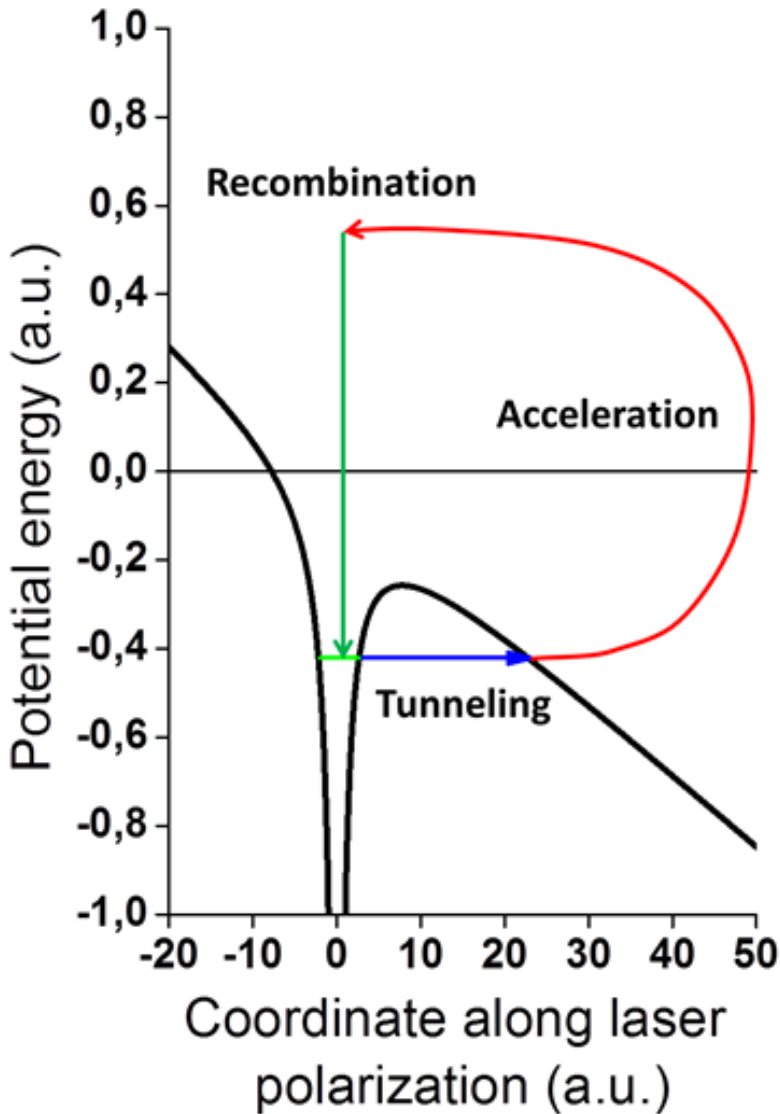

Marc Vrakking

marc.vrakking@mbi-berlin.de

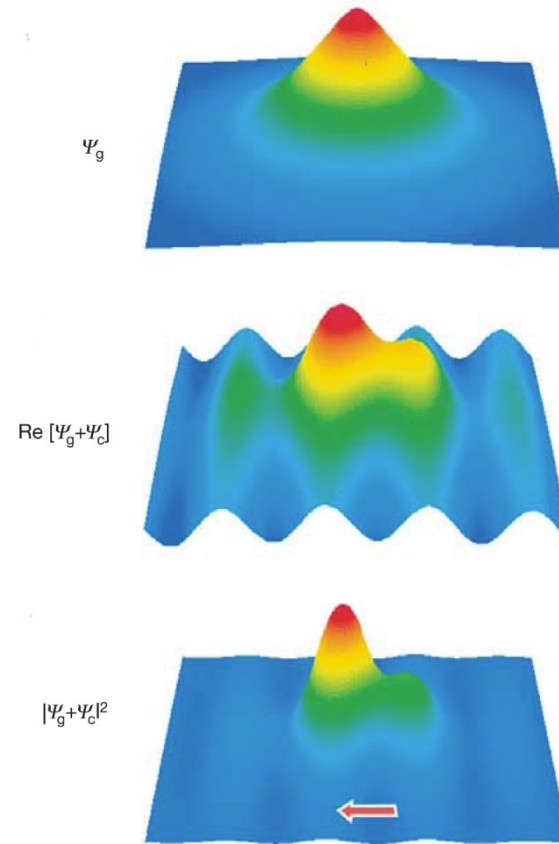

Contents

- High-harmonic generation in molecules
„High –harmonic spectroscopy“
- Attosecond pump-probe spectroscopy in molecules

A quantum-mechanical view of the HHG process

$$d(\omega; \theta) = \langle \psi(\mathbf{r}; \theta) | \mathbf{r} | \exp[ik(\omega)x] \rangle$$

The dipole that leads to harmonic emission arises from interference between the ground state wavefunction and the recolliding electron

Recollision electrons can probe wave functions

Experimentally determined N_2 ground state orbitals (amplitude & phase)

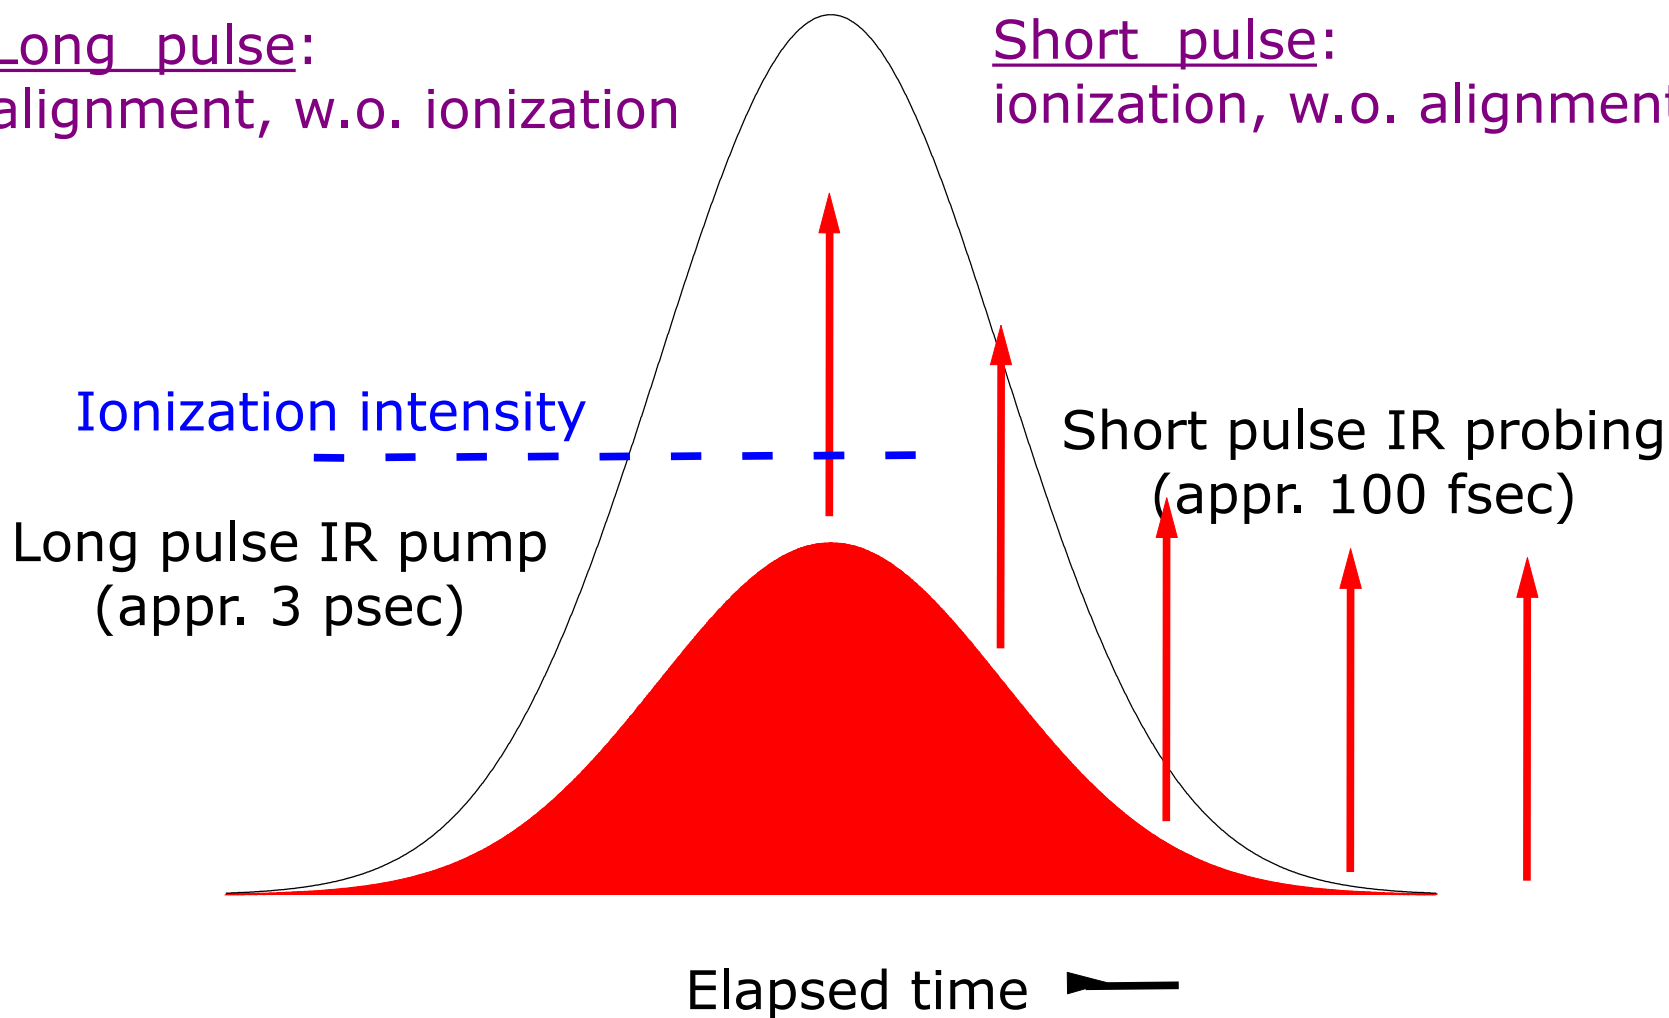

Experiment: HHG in N_2 molecules that are pre-aligned at different angles with respect to the HHG driver laser polarization axis

Itatani et al. 432, 867 (2003)

First impulsive alignment experiment

Long pulse:
alignment, w.o. ionization

Short pulse:
ionization, w.o. alignment

First impulsive alignment experiment

2001: Impulsive molecular alignment (Rosca-Pruna and Vrakking)

Recollision electrons can probe molecular structure

Ionization yield (a) and HHG yield (b,c) in N_2 when the HHG driver pulse is preceded by a pulse that aligns the N_2 internuclear axis: the HHG yield goes **up** when alignment of the molecule gives a **higher** ionization yield

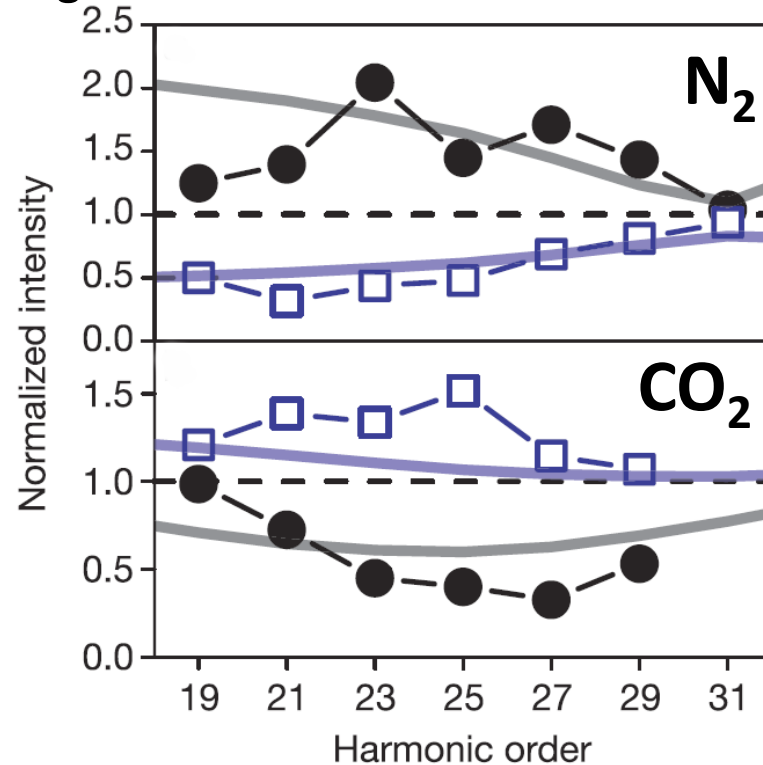

Ionization yield (a) and HHG yield (b,c) in CO_2 when the HHG driver pulse is preceded by a pulse that aligns the CO_2 internuclear axis: the HHG yield goes **up** when alignment of the molecule gives a **lower** ionization yield

Recollision electrons can probe molecular structure

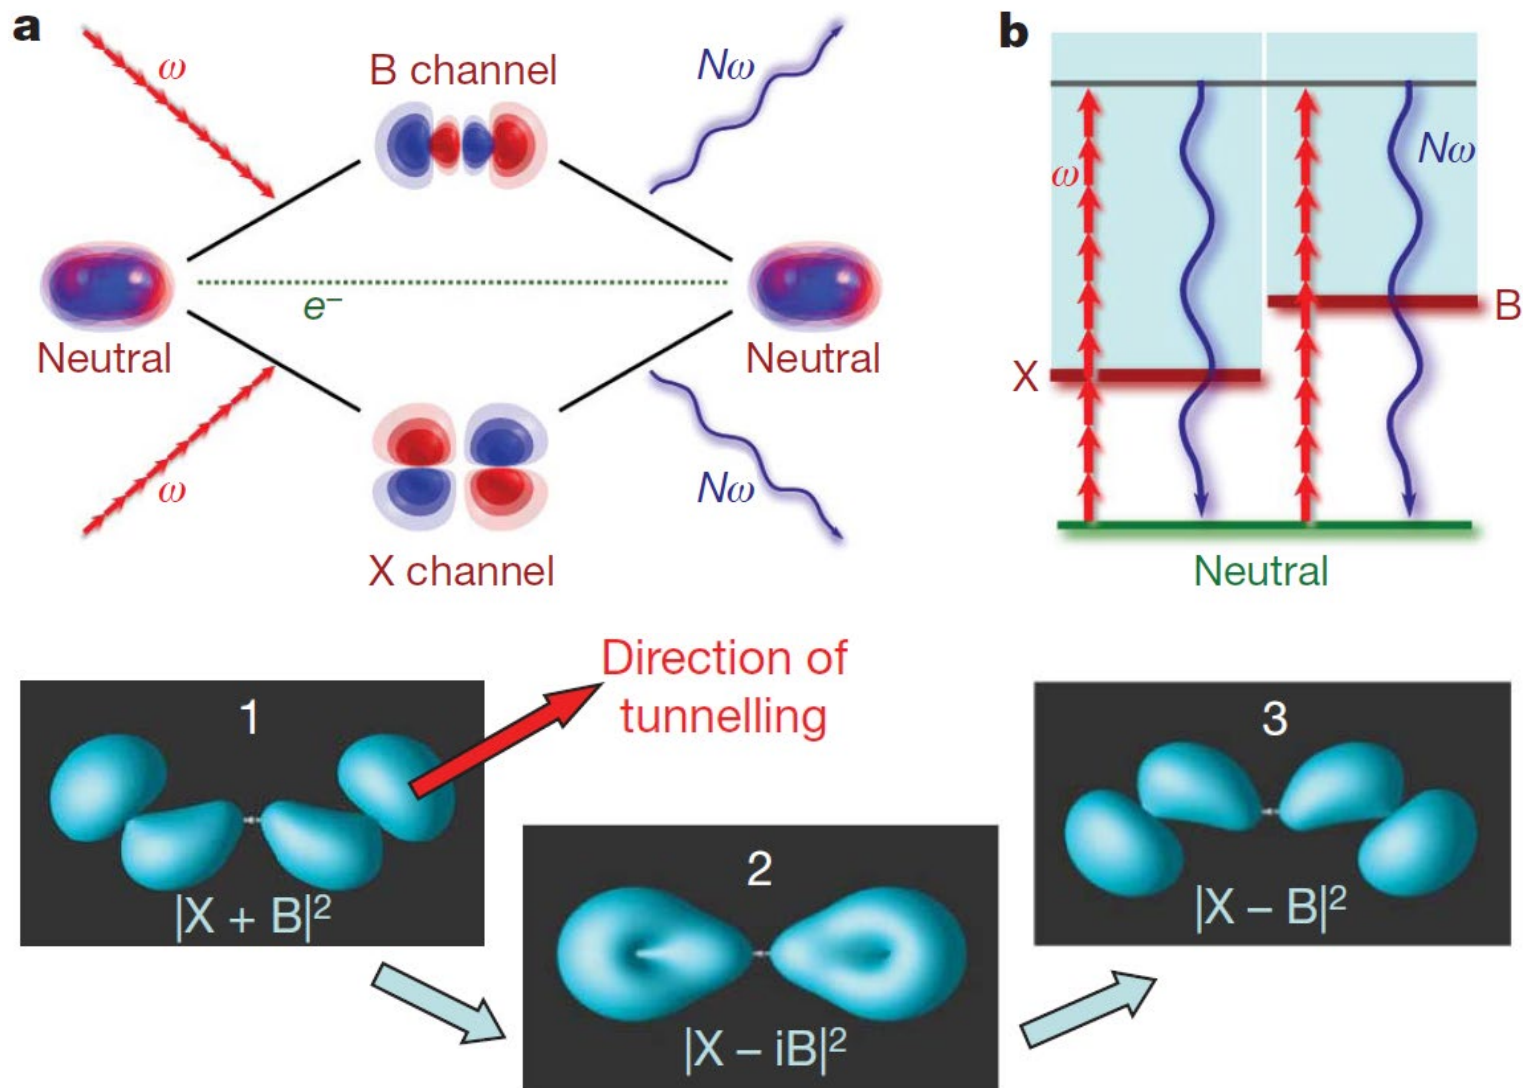

Attractive: the structural information shows up via diffraction, which relaxes the requirements on the availability of spectroscopic knowledge

Diffraction of the recollision electron in the molecular frame shows up in the harmonic yield versus alignment angle.

- Ionization enhanced
- Ionization suppressed

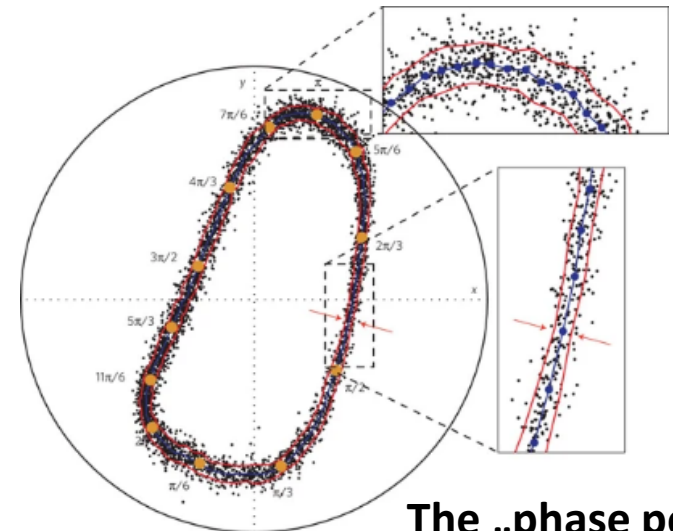

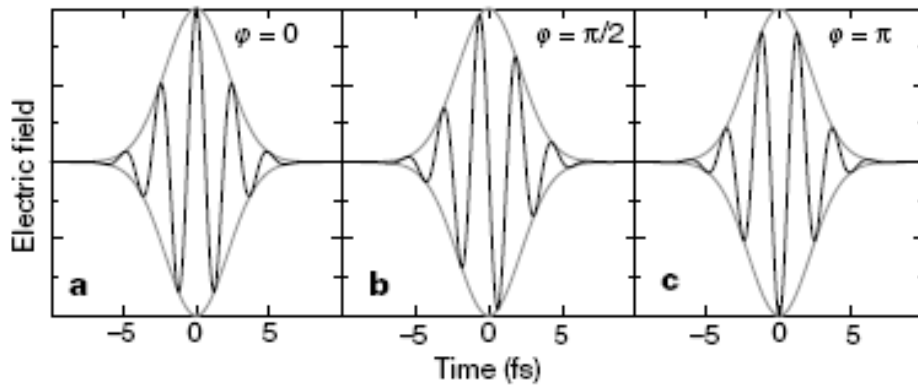

Recollision electrons can probe electron dynamics

Contents

- Attosecond pump-probe spectroscopy in molecules

Lecture M2: CEP Effects in Atomic Ionization

The „phase potato“

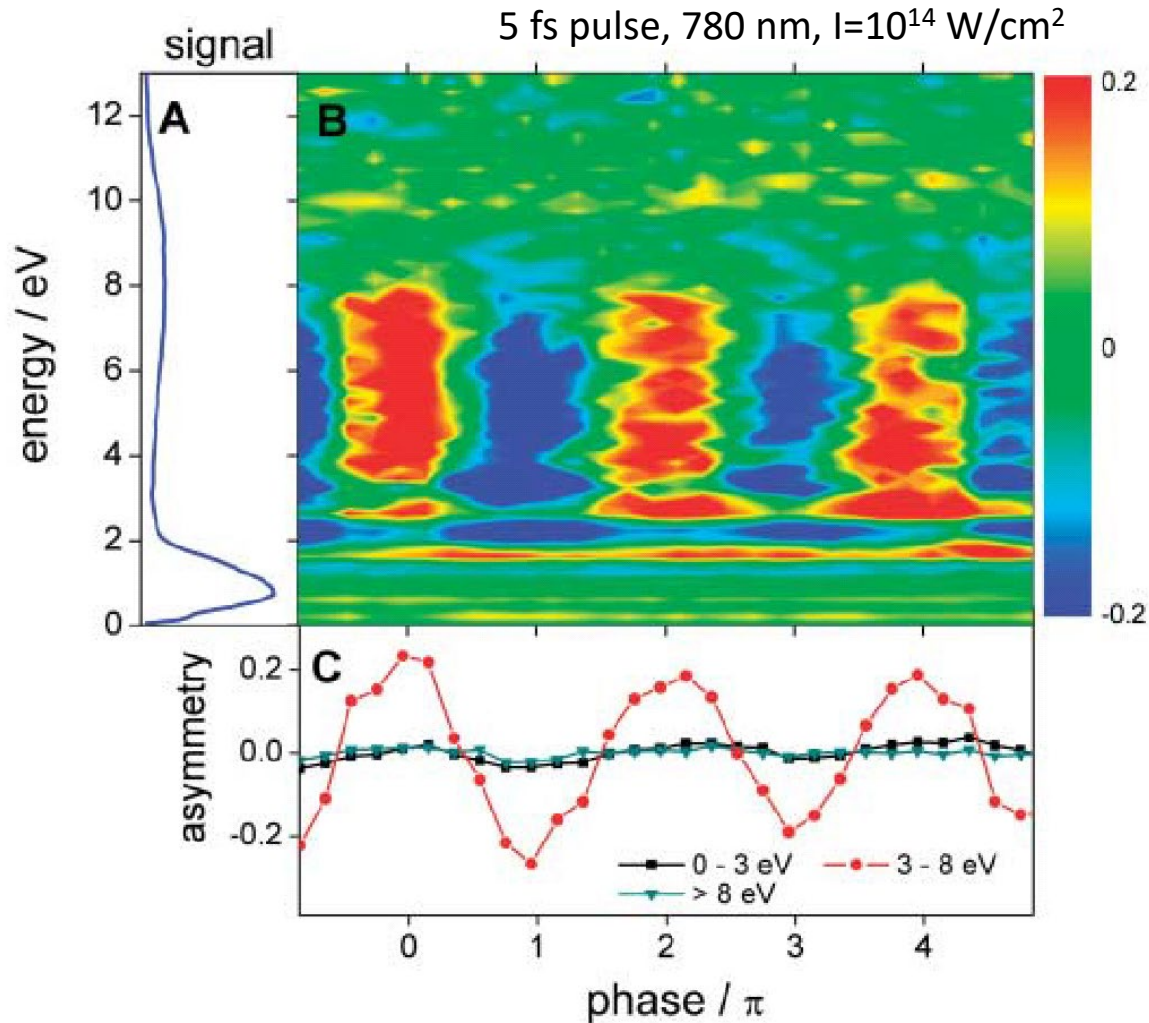

Can carrier envelope phase control electron motion *inside* molecules?

Attosecond electron dynamics in molecules CEP control of electron localization

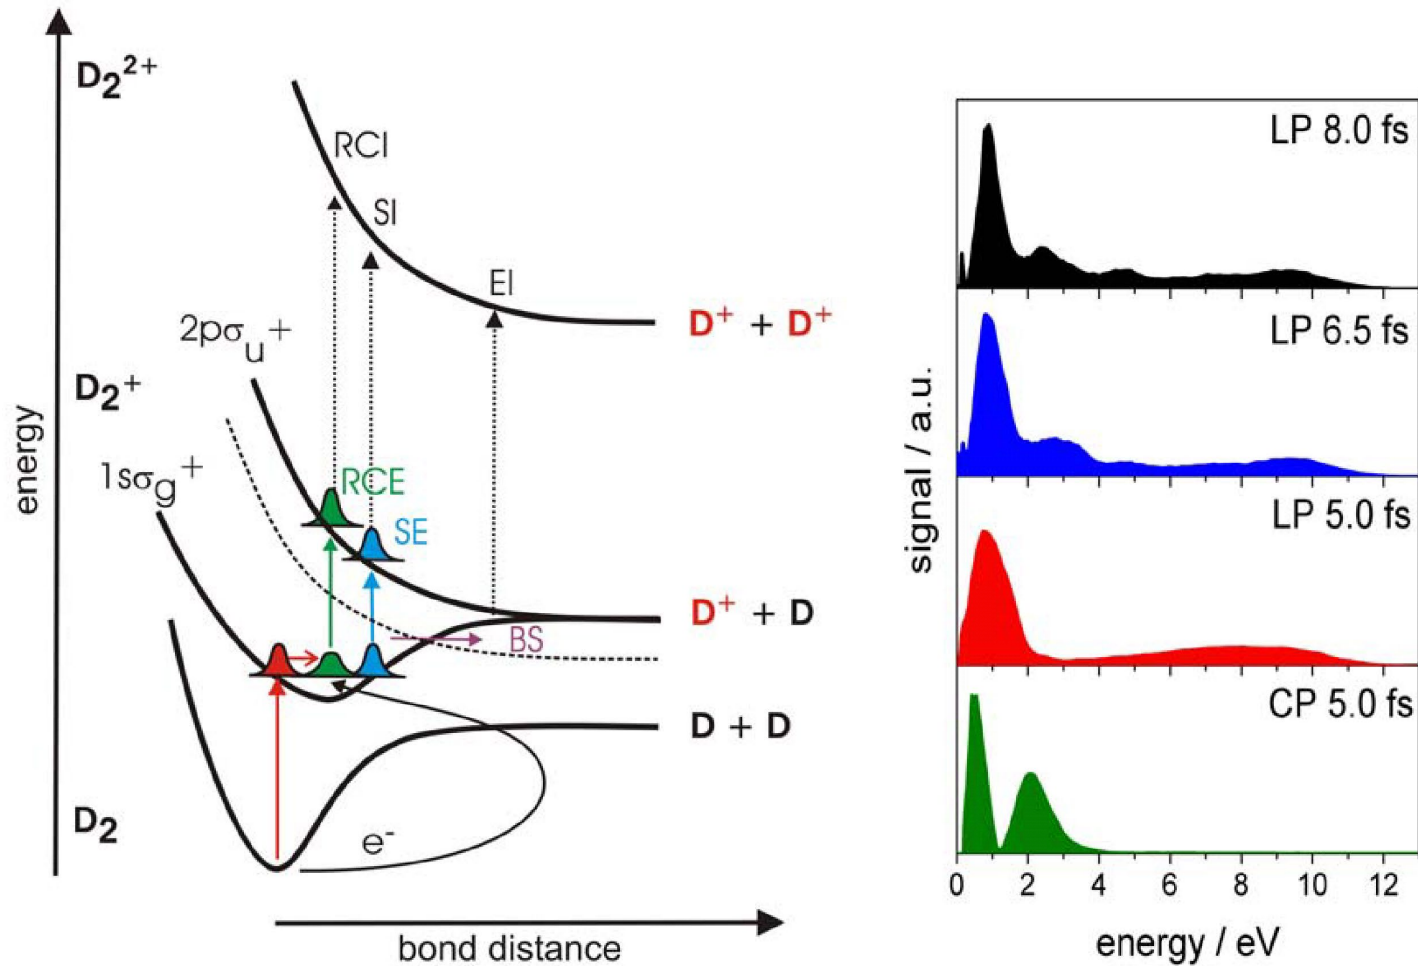

Angle-resolved D^+ ion imaging using CEP-locked few-cycle laser pulses (w. Ferenc Krausz)

Asymmetry $(D^+_{up} - D^+_{down}) / (D^+_{up} + D^+_{down})$

Phase Control Mechanism

Recollision-induced population of the $2p\sigma_u^+$ state

First example of importance of attosecond time-scale electron dynamics in a molecule

Localized States of H_2^+

The $2p\sigma_u^+$ and $1s\sigma_g^+$ states can be viewed as bonding and anti-bonding combinations of $1s$ atomic orbitals

$$\begin{aligned} |g\rangle &= \frac{1}{\sqrt{2}} (|1s_{left}\rangle + |1s_{right}\rangle) \\ |u\rangle &= \frac{1}{\sqrt{2}} (|1s_{left}\rangle - |1s_{right}\rangle) \end{aligned}$$

Therefore, the nuclear wave function can also be expressed on a basis of localized states

$$\begin{aligned} |l\rangle &= \frac{1}{\sqrt{2}} (|g\rangle + |u\rangle) \\ |r\rangle &= \frac{1}{\sqrt{2}} (|g\rangle - |u\rangle) \end{aligned}$$

By projecting onto these states the fraction of the wave function that is on the left or right side of the molecule can be determined

Phase-adiabatic/Quasi-static states

In phase-adiabatic/quasi static states the interaction of the laser field with the molecule is *instantaneously* taken into account.

The phase-adiabatic states are obtained by diagonalization of the potential energy operator \hat{V}

$$\hat{V}(R, t) = \begin{pmatrix} -\omega_0/2 & V_{g,u} \\ V_{g,u} & \omega_0/2 \end{pmatrix}$$

$$V_{g,u} = -\mu(R)E(t)$$

$$\omega_0 = V_u(R) - V_g(R)$$

leading to the following expressions for the phase-adiabatic states

$$V_{1,2}(R, t) = \frac{V_g(R) + V_u(R)}{2} \mp \sqrt{\frac{\omega_0^2}{4} + V_{g,u}^2}$$

Phase-adiabatic/Quasi-static states

Modelling in terms of a sequence of **laser-induced** Landau-Zener transitions

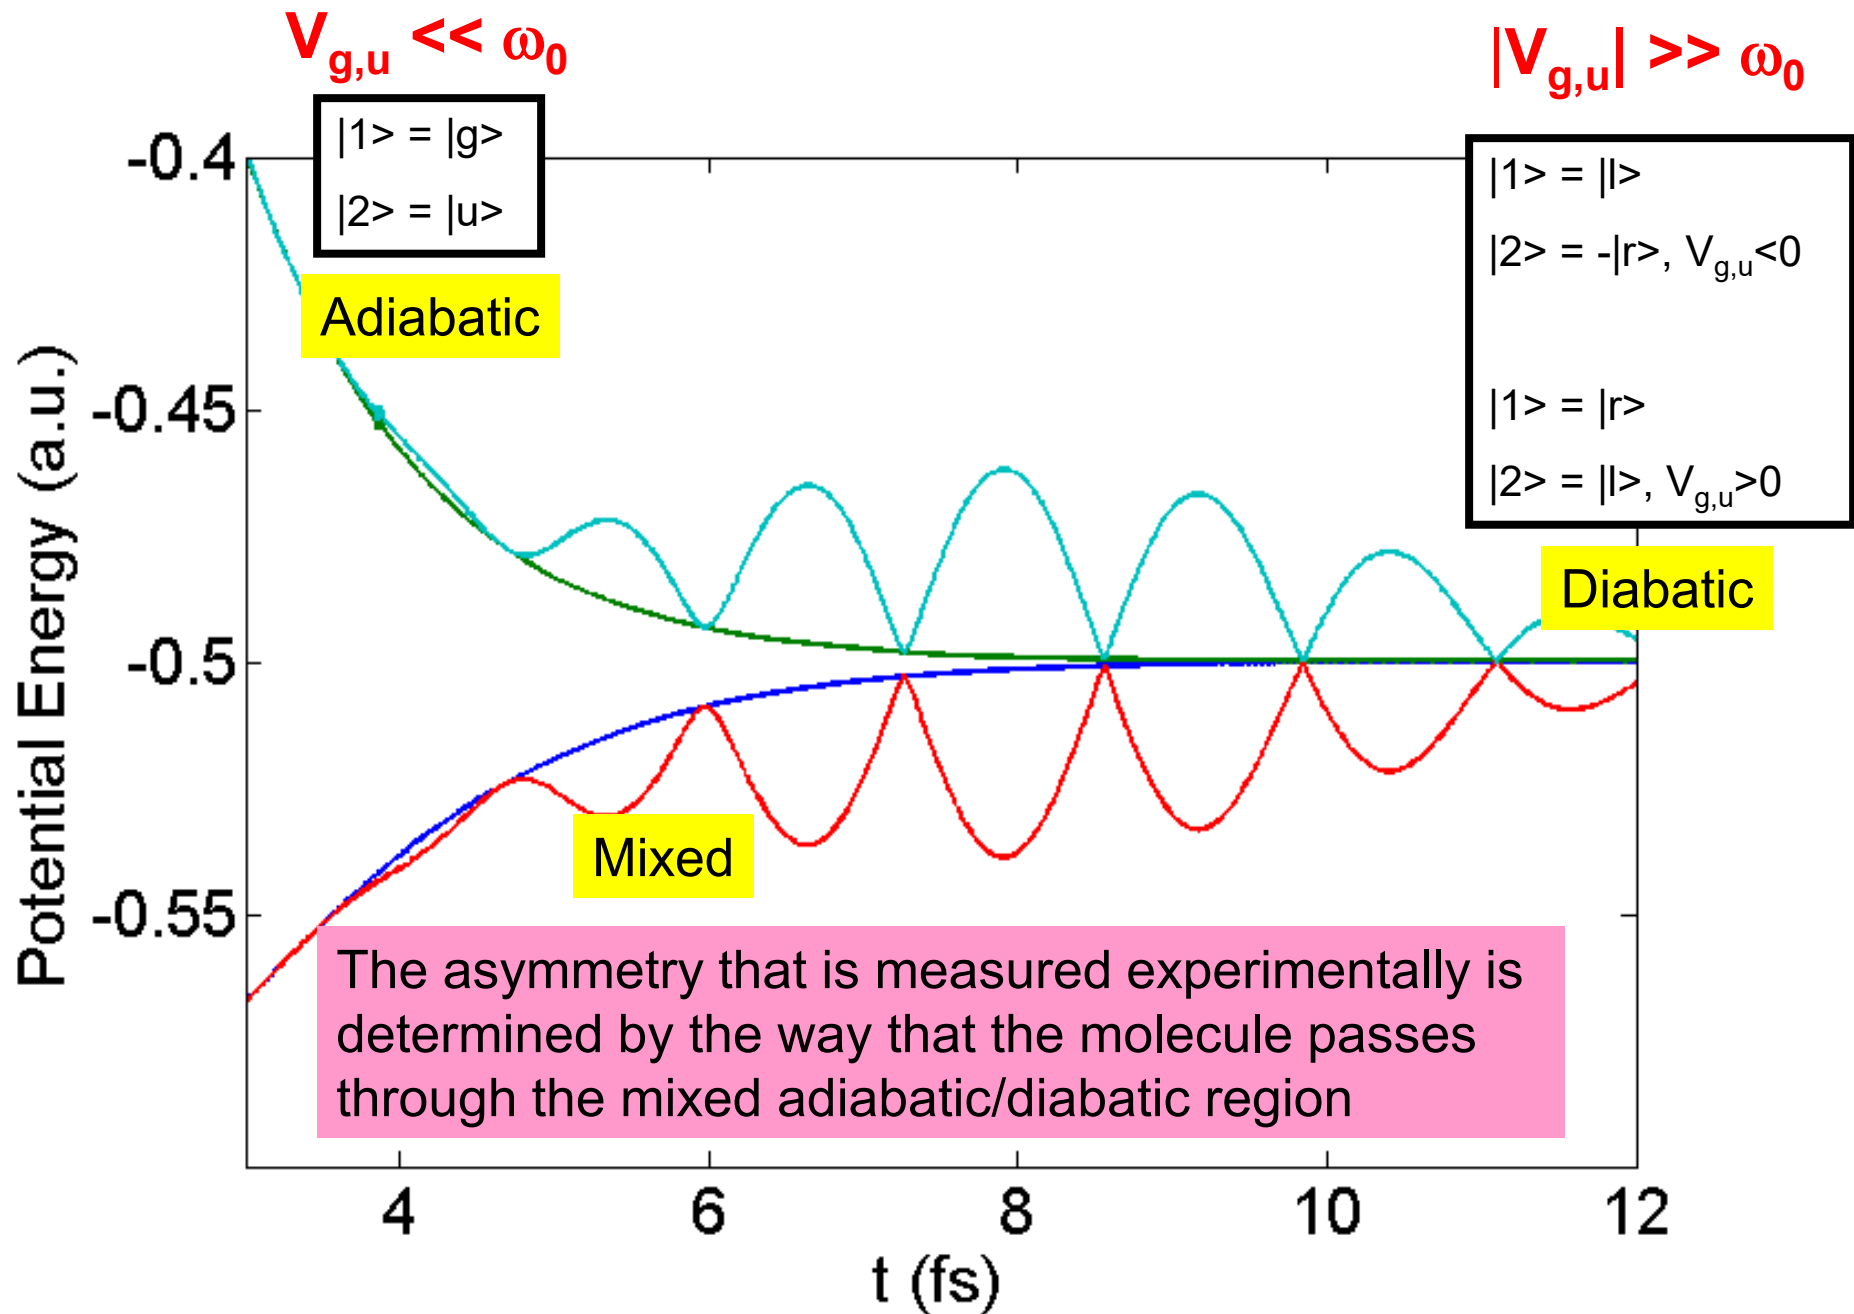

$$W_{1,2} \propto e^{-\frac{\pi \omega_0^2}{4\omega_l \mu E_0}}$$

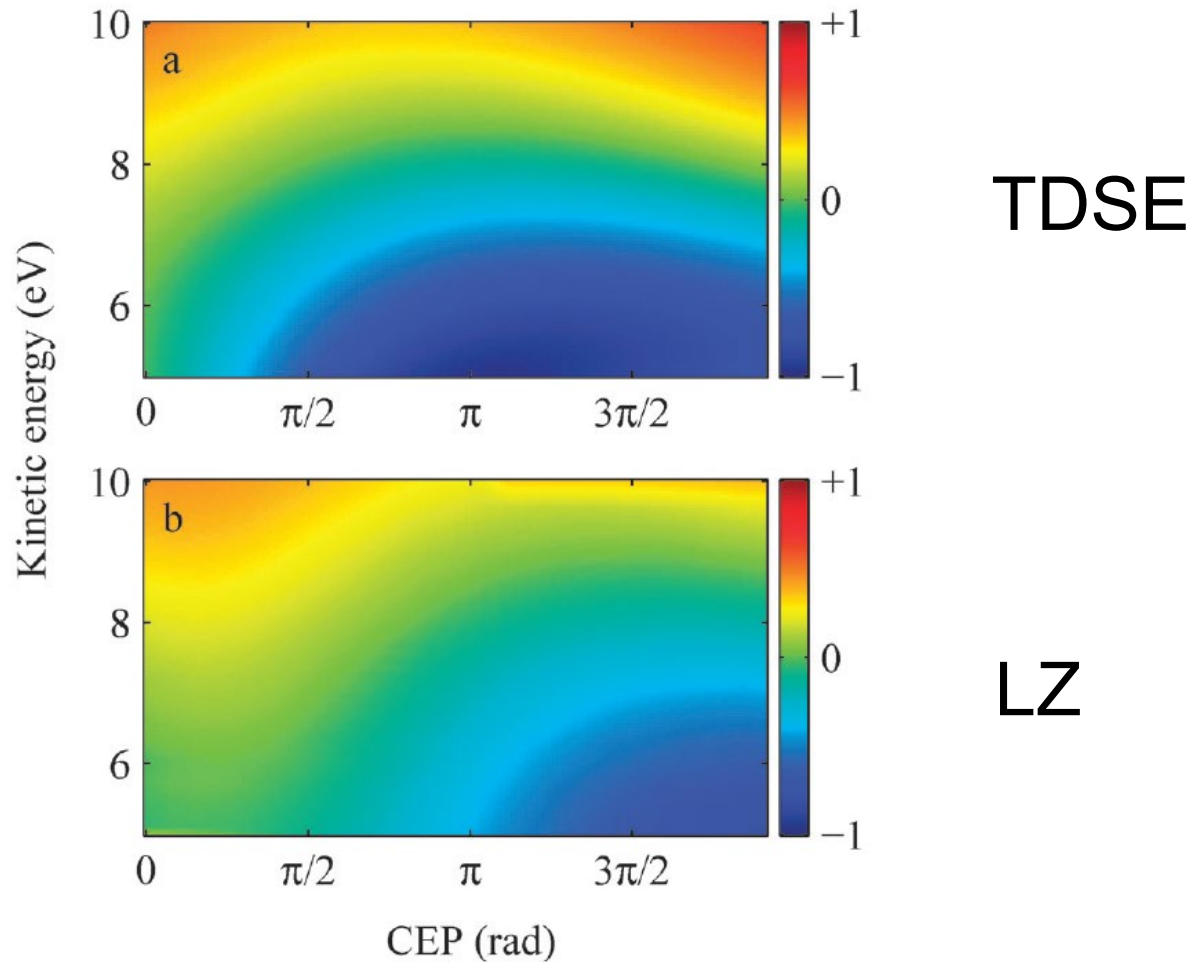

$$\omega_0 = V_u(R) - V_g(R)$$

$$E(t) = E_0 \sin \omega_l t$$

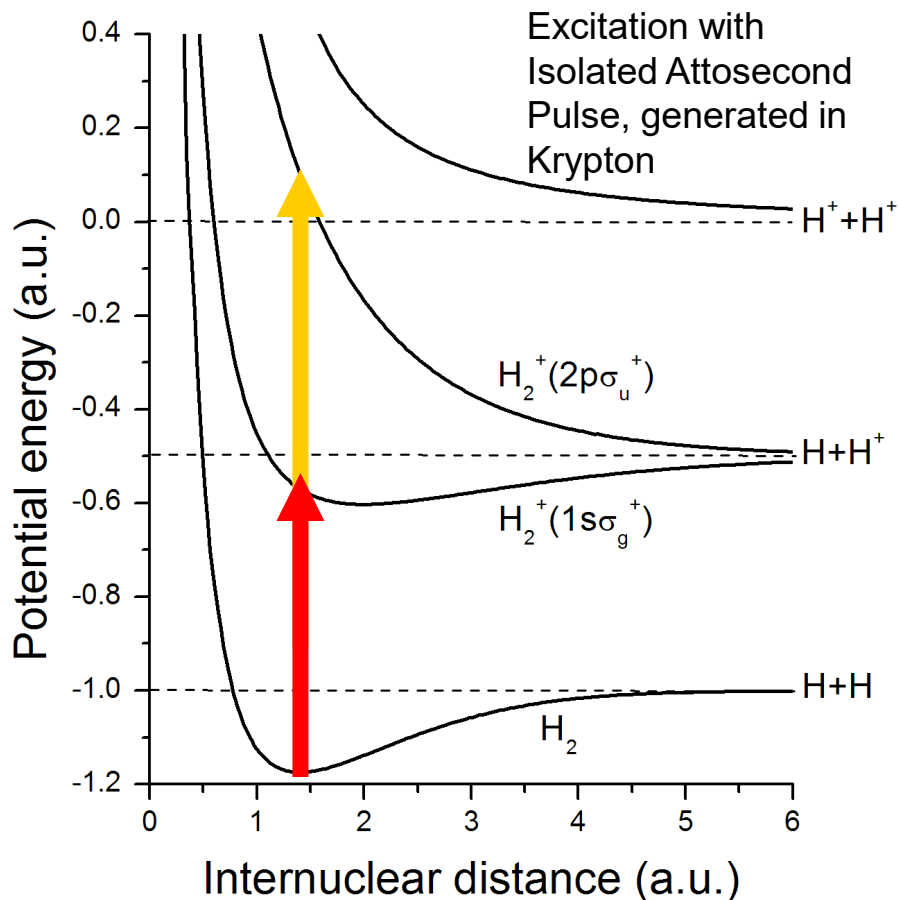

Sequence of Landau-Zener crossings and propagation in the laser field

Energy dependence of the asymmetry using Landau-Zener formulation

XUV-IR Pump-probe experiments on H_2 and D_2

Use isolated attosecond pulse generated in Krypton to launch a wavepacket on the $2p\sigma_u^+$ state or the $1s\sigma_g^+$ state and investigate the subsequent IR interaction

Electron localization in XUV-IR dissociative ionization of H₂ and D₂

Electron localization in H_2^+

$$\psi_g = (1/\sqrt{2})\{\psi_{left} + \psi_{right}\}$$

$$\psi_u = (1/\sqrt{2})\{\psi_{left} - \psi_{right}\}$$

Rewrite

$$\psi_{left} = (1/\sqrt{2})\{\psi_g + \psi_u\}$$

$$\psi_{right} = (1/\sqrt{2})\{\psi_g - \psi_u\}$$

The observation of electron localization requires that the parity of the ionic wavefunction is broken

Consider the wavefunction of the ion+electron

$$\Psi = c_1[\psi_g \epsilon l_g]_g + c_2[\psi_g \epsilon l_u]_u + c_3[\psi_u \epsilon l_u]_g + c_4[\psi_u \epsilon l_g]_u$$

Rewrite

$$\begin{aligned} \Psi = & \frac{1}{2}\sqrt{2}(c_1 + c_4)\psi_l \epsilon l_g + \frac{1}{2}\sqrt{2}(c_2 + c_3)\psi_l \epsilon l_u \\ & + \frac{1}{2}\sqrt{2}(c_1 - c_4)\psi_r \epsilon l_g + \frac{1}{2}\sqrt{2}(c_2 - c_3)\psi_r \epsilon l_u \end{aligned}$$

Determine the probability the bound electron / fragment ion is found on the right or on the left.

Consider the wavefunction of the ion+electron

$$\Psi = \frac{1}{2}\sqrt{2}(c_1 + c_4)\psi_{l_e} \epsilon_{l_g} + \frac{1}{2}\sqrt{2}(c_2 + c_3)\psi_{l_e} \epsilon_{l_{gf}} + \frac{1}{2}\sqrt{2}(c_1 - c_4)\psi_{r_i} \epsilon_{l_{gg}} + \frac{1}{2}\sqrt{2}(c_2 - c_3)\psi_{r_i} \epsilon_{l_{gu}}$$

$$I_{l_e} = \frac{1}{2}|c_1 + c_4|^2 + \frac{1}{2}|c_2 + c_3|^2 \quad I_{r_i} = \frac{1}{2}|c_1 - c_4|^2 + \frac{1}{2}|c_2 - c_3|^2$$

Dipole selection rules **forbid** that a difference occurs between I_{left} and I_{right} in single-photon ionization, since c_1 and c_3 are zero

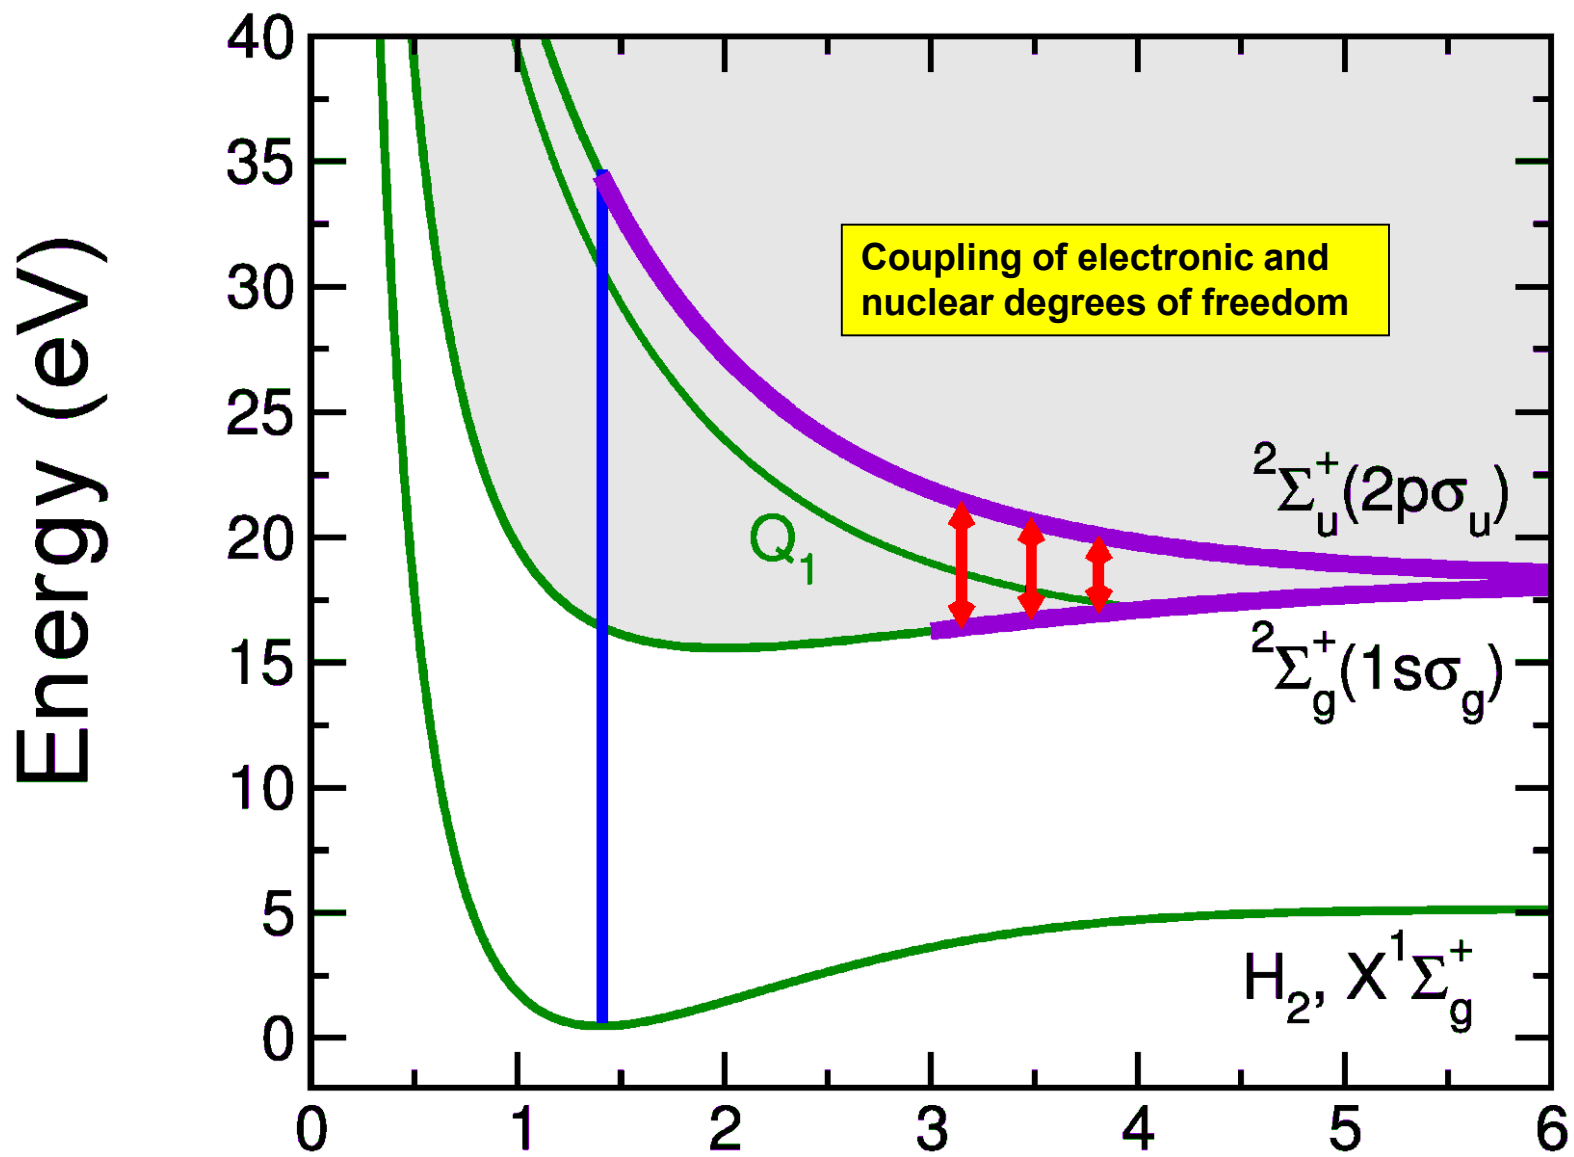

Consider the wavefunction of the ion+electron

$$\Psi = c_1[\cancel{\psi_g \epsilon l_g}]_g + c_2[\psi_g \epsilon l_u]_u + c_3[\cancel{\psi_u \epsilon l_u}]_g + c_4[\psi_u \epsilon l_g]_u$$

We can imagine two ways to construct a coherent superposition of the „g“ and „u“ state starting from this wavefunction

- (1) Use the laser to convert „g“ into „u“ or „u“ into „g“ (remember electron localization with CEP-stable few-cycle pulses)
- (2) Take one of the allowed terms in the expression shown above and change the angular momentum of the photoelectron from „u“ to „g“ or from „g“ to „u“

Mechanism I

Once more: Phase-adiabatic/Quasi-static states

In phase-adiabatic/quasi static states the interaction of the laser field with the molecule is *instantaneously* taken into account.

The phase-adiabatic states are obtained by diagonalization of the potential energy operator \hat{V}

$$\hat{V}(R, t) = \begin{pmatrix} -\omega_0/2 & V_{g,u} \\ V_{g,u} & \omega_0/2 \end{pmatrix}$$

$$V_{g,u} = -\mu(R)E(t)$$

$$\omega_0 = V_u(R) - V_g(R)$$

leading to the following expressions for the phase-adiabatic states

$$V_{1,2}(R, t) = \frac{V_g(R) + V_u(R)}{2} \mp \sqrt{\frac{\omega_0^2}{4} + V_{g,u}^2}$$

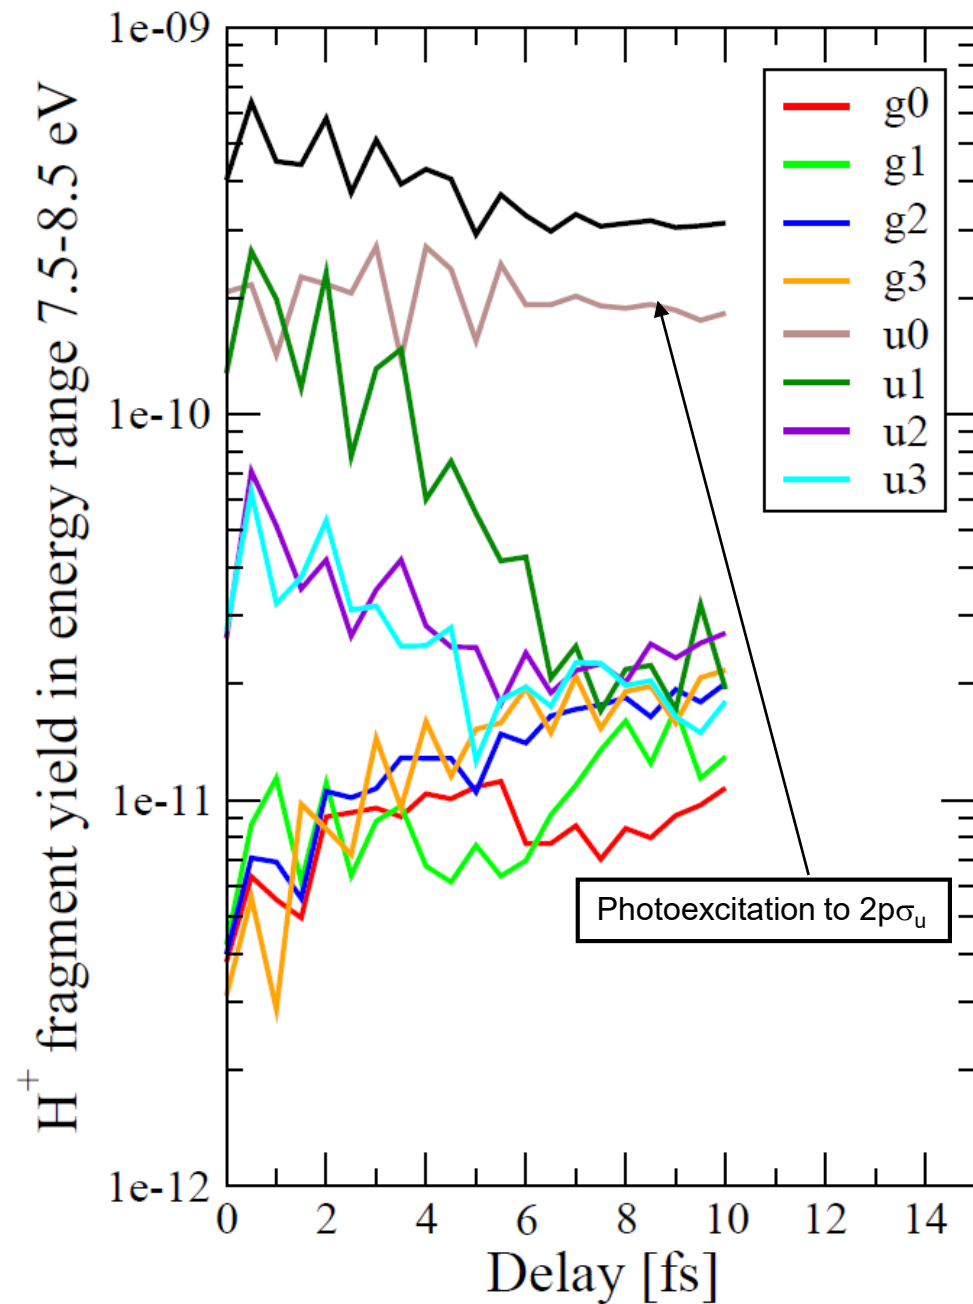

Energy dependence of the asymmetry using Landau-Zener formulation

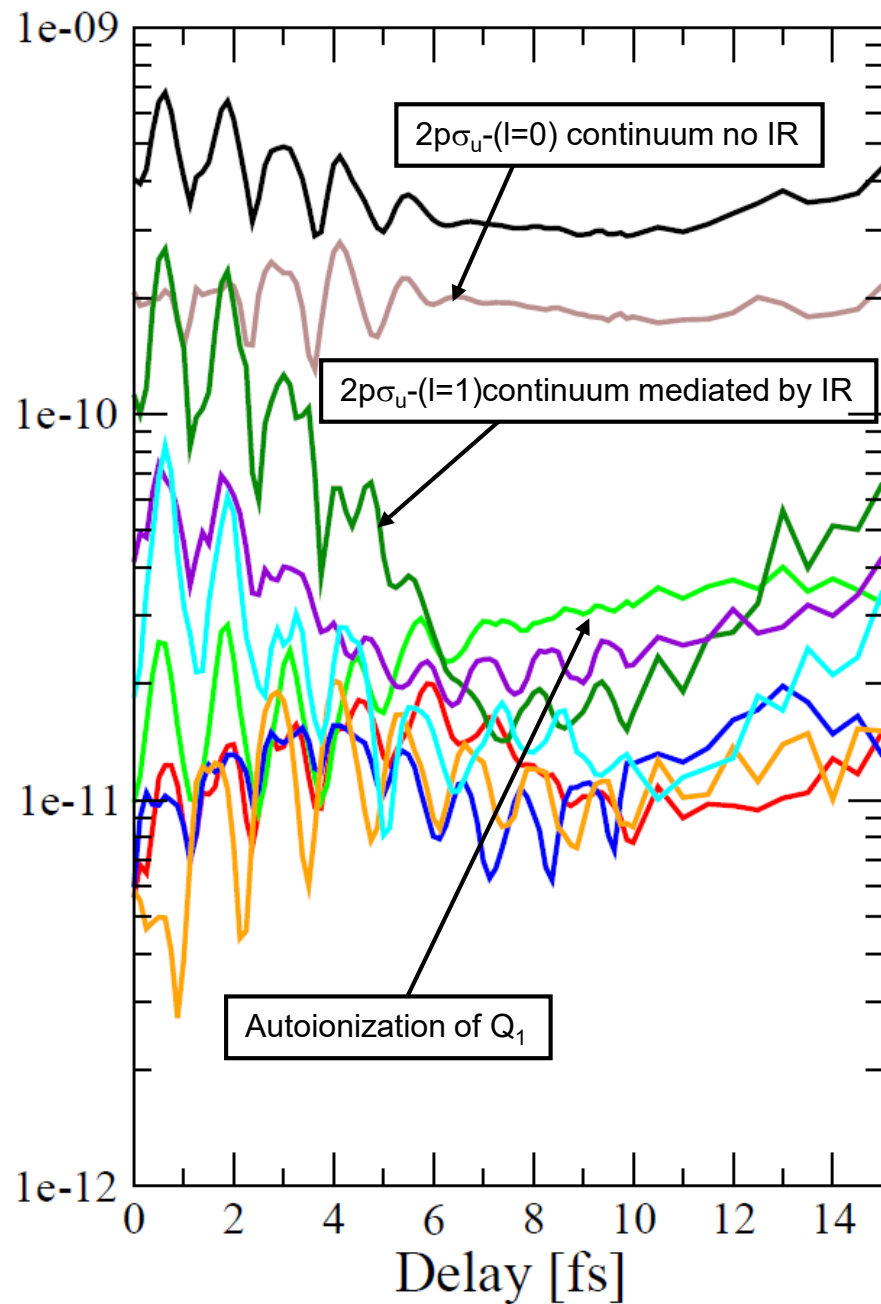

Collaboration with F. Martin and co-workers

Without the auto-ionizing states

Full calculation

Mechanism II

The Holy Grail: Attosecond electron dynamics in complex molecules

Charge migration upon sudden ionization (Glycine II):

Coherent preparation of ionic states

Kuleff & Cederbaum, Chem Phys 338, 320 (2007)

Attosecond electron dynamics in a molecule

Leu-γ

Gly-γ

Tryptophan

IP ~ 7.5 eV

$\lambda_{OPT} = 286.7$ nm

Tyrosine

IP ~ 8.0 eV

$\lambda_{OPT} = 281.7$ nm

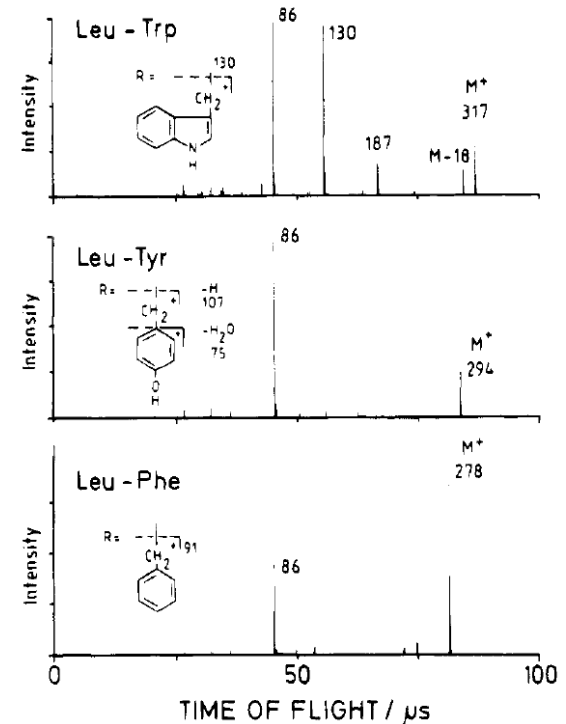

Phenylalanine

IP ~ 8.4 eV

$\lambda_{OPT} = 266.4$ nm

a molecule

After selectively ionizing a chromophore on the C-terminal end of the peptide ionic fragmentation patterns resulting from additional UV absorption were dominated by ionic species related to the N-terminal end of the peptide

Interpreted in terms of efficient *charge migration* (i.e purely electronic motion, not involving the nuclei) from the N-terminal end of the peptide to the chromophore

Weinkauff et al., *J. Phys. Chem.* **99**, 11255 (1995)

Electron correlation-induced charge migration

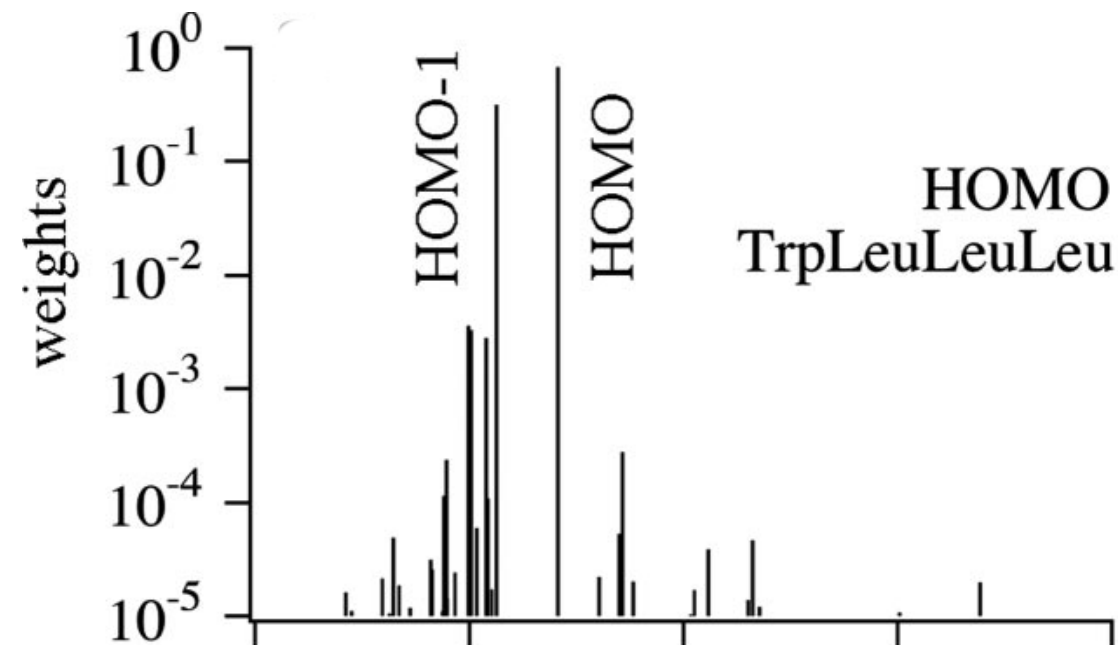

Koopmans' theorem: the first ionization energy of a molecular system is equal to the negative of the orbital energy of the highest occupied molecular orbital (HOMO)

→ Removal of single electrons requires a certain amount of energy and leaves the orbitals of all other electrons *unchanged*.

Attosecond dynamics in molecules can result from a breakdown of Koopmans theorem

→ Removal of single electrons leads to the excitation of multiple ionic states, which have different energies → coherent evolution of the hole in the charge density without participation of nuclear degrees of freedom („charge migration“)

Example: TrpLeu₃ complex

The highest-occupied-molecular orbital (HOMO) of TrpLeu₃ ionizes predominantly into the ground (HOMO) and first excited (HOMO-1) state of the cation, which are separated by 2.84 eV (0.105 a.u.)

Anticipate beat period of $2\pi/\Delta E = 60$ a.u. = 1.45 fs

[Remacle & Levine, PNAS 103 6793 \(2006\)](#)

First experimental demonstration?

Phenylalanine → Doubly-charge immonium

“The yield of immonium dications is a particularly sensitive probe of charge location because the local ionization potential will increase as the hole approaches the amine group causing ionization by the VIS/NIR pulse to be suppressed.”

Yes: First experimental demonstration

Phenylalanine → Doubly-charge immonium

“The yield of immonium dications is a particularly sensitive probe of charge location because the local ionization potential will increase as the hole approaches the amine group causing ionization by the VIS/NIR pulse to be suppressed.”

Transient absorption with femtosecond time-resolution and atomic specificity

Before dissociation

„molecular“

After dissociation

„atomic“

Transient absorption with attosecond time-resolution and atomic specificity

Transient absorption with as time-resolution and atomic specificity

Dominant response now on Rydberg states, rather than valence states!
